Modern systems struggle to manage user attention effectively in environments filled with

constant notifications and fragmented applications, where frequent, poorly timed alerts and disconnected workflows disrupt focus, reduce productivity, and degrade overall user experience. Current solutions lack the ability to understand real-time user context—such as active tasks, behavior, and interaction patterns—and fail to determine whether a notification should be delivered, delayed, or suppressed. At the same time, they do not provide a seamless way to handle actions across multiple independent applications, forcing users to switch between platforms to manage tasks and information. This results in unnecessary interruptions and inefficient workflows. Addressing this unified challenge is critical across mobile applications, productivity tools, enterprise platforms, and smart environments, where optimizing attention and enabling smooth, context-aware interactions are essential for a cohesive and efficient user experience.
this is the problem statement i got for an 24hr hackathon.
the uploaded image is my understanding and solution for this PS..
1.rate the PS on provided solution
2. document the my provided solution in a fully explanable mannar
3. suggest additional features or tech that we can add upto this to make it an hackathon MVP winner.
4.feasibilty and techstack for each features

Your handwritten notes effectively capture the core problem of fragmented notifications and apps, proposing a smart system to address it.

Solution Rating

Your solution rates 8/10 against the problem statement. It directly tackles context-aware notification timing and unified app actions via a "super app layer," aligning well with attention management and seamless workflows. Minor gaps include lacking specifics on real-time context detection (e.g., user activity) and cross-platform handling, but the high-level architecture is innovative for a hackathon.[1] [2]

Documented Solution

Core Concept

Create a "super app layer" (unified system) that sits atop fragmented applications and notification ecosystems. This intelligent overlay monitors user behavior, task context, and app states to deliver or suppress alerts intelligently.

Key Mechanism

- **Context Engine**: Analyzes real-time signals like active tasks, interaction patterns, and environmental factors to decide notification fate—deliver now, delay (e.g., for a month or until relevant), or suppress entirely.
- **Unified Action Hub**: Enables cross-app actions without switching; e.g., a notification from App A triggers seamless handling in App B via the layer.
- **Smart Delivery**: Uses ML-based rules for "perfect timing," reducing disruptions while ensuring critical info reaches users.[2]

Workflow Example
User focuses on Task X in App 1; incoming App 2 notification gets delayed until Task X ends or context matches, then executes unified action (e.g., save data across apps).

This architecture unifies mobile/productivity/enterprise environments into a cohesive experience.[3]

Winning Features

AI-Powered Context Detection
Add on-device ML to infer user state (e.g., focused, walking, meeting) using sensors like accelerometer, screen time, and app usage. Demo with phone tilt/do-not-disturb simulation.

Cross-App Action Automation
Integrate no-code triggers (e.g., Zapier-like) for notifications to auto-execute actions across apps, like "email reply → calendar add."

Attention Dashboard
Visual dashboard showing daily focus score, suppressed notifications summary, and customizable rules (e.g., "delay social media during work").

Voice/Command Integration
Natural language handling for notifications via voice (e.g., "Snooze emails till evening") using speech-to-text.

Gamification & Insights
Reward streaks for uninterrupted focus with badges; generate weekly reports on productivity gains.

These elevate to MVP winner by showing real demo-ability and user delight.[4] [3]

Feasibility & Tech Stack

Feature	Feasibility (24hr Hackathon)	Tech Stack
AI Context Detection	High (use pre-trained models)	React Native/Flutter frontend; TensorFlow Lite/ML Kit for on-device inference (activity recognition); Firebase for quick backend sync.[2] [4]
Cross-App Automation	Medium (mock integrations)	Node.js/Express backend; Firebase Functions for triggers; Mock APIs for 2-3 apps (e.g., simulate Gmail/Calendar via JS SDKs).[3]

Feature	Feasibility (24hr Hackathon)	Tech Stack
Attention Dashboard	High (UI-focused)	React Native with Charts.js/Recharts; Local storage via AsyncStorage; Expo for fast mobile build/deploy.
Voice Integration	Medium-High (basic)	Expo Speech + React Native Voice; Offline processing with Web Speech API fallback.
Gamification/Insights	High (simple logic)	Local SQLite/Realm DB; Plotly or native charts; Gamification via state management (Redux/Context API).[3]

All feasible with Expo/React Native for cross-platform MVP deployable to phones in hours; total stack: free/low-cost, no heavy infra needed.[3]

⁂

the idea i had is an application where we can add all the tools that a user might use like if user role is an data analyst then he might use maximum of Whatsapp for updates, microsoft teams for team meetings, power BI for productivity and an browser for research...

so how can this super top application integrate with this fragmented application and communicate with all of them and if possible allow to communicate within themselves... what is the feasibilty ? if yes for an MVP for just this mentioned apps then what should be the flow and architecture...
with the above mentioned and suggested features of yours for it!

A super app layer can integrate with WhatsApp, Teams, Power BI, and browser via APIs, SDKs, and extensions, enabling unified notifications, cross-communication, and actions for a data analyst role.

Integration Methods

WhatsApp: Use WhatsApp Business Cloud API for sending/receiving messages and webhooks for incoming notifications. Requires Meta developer account and phone number verification (sandbox mode for hackathon).[12] [13]

Microsoft Teams: Deploy a Bot Framework bot to post/receive messages in channels/chats; use proactive messaging for notifications and Graph API for deeper access like calendar integration.[14] [15]

Power BI: Embed reports/dashboards via Power BI JavaScript Embed API with AAD tokens; fetch data/insights programmatically for unified views or triggers.[16] [17]

Browser (Research): Chrome/Firefox extension with content scripts to capture tab activity, send summaries/notifications; communicate via messaging API to super app.[18]

Cross-Communication: Super app acts as central hub—poll webhooks or use real-time channels (e.g., Socket.io) to relay data between apps (e.g., WhatsApp update → Teams alert → Power BI refresh).[19]

MVP Feasibility

High feasibility for 24hr hackathon (8/10): Use free tiers, sandboxes, and mocks for auth-heavy APIs. Full prod integration needs approvals (WhatsApp/Teams), but MVP demos with test accounts, simulated data, and local polling. Prioritize 2-3 apps if time-constrained; browser extension quickest to prototype.[12] [19]

Architecture Overview

Modular micro-frontend with React Native (mobile-first for analyst workflows), Node.js backend for orchestration.

```
Frontend (Super App): React Native/Expo
├── Unified Dashboard (tabs for WhatsApp/Teams/PowerBI/Browser)
├── Notification Center (context-aware queue)
├── Action Hub (cross-triggers)
└── Extension Bridge (for browser)

Backend: Node.js + Express + Firebase Functions
├── Webhook Receivers (WhatsApp/Teams)
├── API Gateways (PowerBI Embed tokens, Graph API)
├── Context ML (TensorFlow.js Lite)
└── Real-time Sync (Socket.io/WebSockets)

Integrations:
- WhatsApp: Cloud API Webhooks → Firebase
- Teams: Bot Adapter → Graph API
- PowerBI: JS Embed + REST API
- Browser: Chrome Ext → Native Messaging/Socket

Data Flow: Sensors/App APIs → Context Engine → Decide/Delay/Suppress → Unified Action
```

Deploy: Expo for app, Vercel/Netlify for backend, ngrok for local webhooks.[19]

User Flow

1. **Onboard**: User adds apps (OAuth for Teams/PowerBI, WhatsApp sandbox QR, install browser ext).
2. **Monitor**: Super app polls/subscribes to events (e.g., new WhatsApp message, Teams mention, PowerBI alert, browser tab switch).
3. **Context Check**: ML assesses focus (e.g., active in PowerBI → suppress WhatsApp).
4. **Notify Unify**: If deliver, show in dashboard; enable actions like "Reply on WhatsApp + Log in Teams + Refresh PowerBI."

5. **Cross-Actions**: E.g., Teams meeting update auto-saves to PowerBI dashboard; browser research snippet shares to WhatsApp group.[20]

Incorporated Features

AI Context Detection: TensorFlow Lite detects app focus, device motion (e.g., suppress during Teams call).[from prev]

Cross-App Automation: Firebase Functions trigger chains (WhatsApp text → Teams post → PowerBI update).

Attention Dashboard: Charts focus time, app switches; embed PowerBI for analyst viz.

Voice Integration: Expo Speech for "Send update to team" → routes to Teams/WhatsApp.

Gamification: Local streaks for "no interruptions" during analysis sessions.

This MVP demos end-to-end for data analyst: unified inbox → smart actions → productivity boost.[from prev] [19]

Tech Stack & Timeline

Component	Tech	24hr Effort
Frontend	React Native/Expo	6-8hrs (dashboard + embeds)
Backend	Node.js, Firebase Auth/Functions	4-6hrs (webhooks + logic)
Integrations	WhatsApp Cloud API (sandbox), MS Graph/Botkit, PowerBI Embed JS, Chrome Ext (Manifest V3)	6-8hrs (mocks first)
ML/Context	TensorFlow.js Lite, Expo Sensors	2-3hrs
Deploy	Expo EAS, ngrok, Vercel	1hr

Total: ~20hrs; test with mock data for speed.[16] [12]

⁂

now you suggested for an web extension.. for a data analyst all tools that he might use is available in web... like whatsapp, teams, powerbi etcc... but for an video editor using premier pro or an software devleoper using VS code those are offline apps that works on application level.. how can we cater themm how can we get that data from those offline applicationsss..!!!

Offline desktop apps like Premiere Pro and VS Code can be integrated via custom extensions, SDKs, OS-level hooks, and IPC for notifications, activity tracking, and cross-communication in your super app layer.

Integration Strategies

Custom Extensions (Primary Method)
Build lightweight extensions/panels that hook into app events and forward data to your super app via WebSockets, local HTTP servers, or OS notifications.

OS Accessibility APIs
Use system APIs to monitor active windows, text selections, or UI elements without app-specific code (fallback for no SDK).

Desktop App as Hub
Your super app runs as a native Electron/Tauri desktop app, using IPC or shared files/sockets to receive from plugins.

These enable pulling notifications, activity (e.g., "editing timeline in Premiere"), and triggering actions.[22] [23] [24]

Premiere Pro (Video Editor)

Data Access:

- **CEP Extension** (JS/HTML/CSS): Create dockable panel for notifications, project events (timeline changes, exports); access via ExtendScript API for playhead position, clip data.
- **C++ SDK Plugin**: Deeper hooks for render status, effects; broadcast via local UDP/WebSocket.
- **Notifications**: Intercept app alerts, suppress/forward to super app.

Forwarding: Extension posts to localhost:port (your super app server) or Firebase Realtime DB for unified queue.[25] [22]

VS Code (Software Developer)

Data Access:

- **VS Code Extension** (TypeScript): Use VS Code API for window active editor, file changes, terminal output, workspace events; send notifications via `vscode.window.showInformationMessage`.
- Track languages/projects via watchers (e.g., aw-watcher-vscode as inspo).

Forwarding: Extension activates local server or uses `exec` to notify Electron super app; integrate with Live Share for collab hints.[23] [26]

Feasibility for MVP

Medium-High (7/10 for 24hr hackathon): Extensions buildable in 2-4hrs each with templates. Demo with mocks (simulate events via timers). Prod needs app installs/signing, but hackathon judges love live demos. Cross-OS (Win/macOS) via Electron; avoid deep C++ for Premiere (stick to CEP).[26] [22]

Architecture Updates

Extend prior mobile/web setup to **Hybrid Desktop Super App** (Electron for cross-platform).

```
Desktop Super App (Electron/Tauri)
├── Tray Icon + Dashboard Window
├── Local Server (Express on port 3000) for IPC
├── Context Engine (TensorFlow.js)
└── Integrations Bridge

App Plugins/Exts:
- Premiere CEP Panel → Socket.io to localhost:3000 (events: "export_done", "timeline_fo
- VS Code Ext → vscode.commands + HTTP POST (events: "file_saved", "debug_start")
- OS Watcher (Fallback): pyautogui/Accessibility API polls active app

Backend Sync (Optional): Firebase for multi-device

Flow: App Event → Plugin → Local Socket/HTTP → Super App Context Check → Unified Notify/
```

Cross-Comm Example: VS Code save → Super app notifies Premiere "Import code-generated assets"; suppress if editing video.[27]

MVP Flow for Roles

1. **Install**: Super app (Electron) + app extensions (VSIX for Code, CEP for Premiere).
2. **Register**: Extensions connect to super app localhost endpoint.
3. **Monitor**: Plugins emit JSON payloads (e.g., `{app: "vscode", event: "focus", file: "script.js"}`).
4. **Context/Actions**: Super app decides (e.g., delay Slack notif during Premiere render); enables "Share VS Code snippet to Premiere notes."

5. **Unified Dashboard**: Role-based tabs (Editor: timeline/projects; Dev: files/languages).

Incorporate prior features: AI context from keystrokes/mouse; voice via Electron SpeechRecognition; dashboard charts app switches.[24]

Tech Stack & Timeline

App/Method	Tech	24hr Effort
Super App	Electron + React + Socket.io	4hrs (boilerplate)
Premiere	Adobe CEP (JS, VS Code template)	3hrs
VS Code	VS Code Extension API (TS, yeoman generator)	2hrs
OS Fallback	Node.js + robotjs (Win) or AppleScript (macOS)	2hrs (basic)
ML	TensorFlow.js for activity patterns	1hr

Total ~12hrs; focus Electron + one ext per role for demo. Use Tauri for lighter native build if time allows.[22] [23] [27]

⁂

so you suggesting to create plugin and extensions for premier pro, photoshop, and v coder!!?? to get the data and comnuicate for the automation system?

also if a video editor has made an export of his video can we send a completioon notification to him after export is completed or if error occured in between!! etccc

Yes, creating targeted plugins/extensions for Premiere Pro, Photoshop, and VS Code is the most reliable way to access internal data, events, and enable automation in your super app—direct OS hooks are limited and brittle.

Why Plugins/Extensions?

Native apps don't expose APIs openly, so extensions provide official hooks for events like saves, errors, exports. They're installable (e.g., VSIX files, CEP folders), run in-app, and communicate via local sockets/IPC to your super app without root access. Hackathon-friendly: templates exist, debuggable in VS Code.[32] [33] [34]

Premiere Pro: Export Notifications

Yes, fully possible to detect and notify on export completion, errors, progress.

Via CEP Extension (JS):

- Poll ExtendScript: Use `app.encoder` or project events to check queue status (initiated, encoding, done/error).

- Callbacks: Hook into export via scripting (e.g., monitor `Exporter` suite indirectly via timers/polling since direct events limited in CEP).
- Example Payload: `{event: "export_complete", file: "video.mp4", duration: "2min", status: "success"}` or `{status: "error", reason: "codec_fail"}`.

Send to super app via `fetch('http://localhost:3000/notify')` or Socket.io. Users start export natively; extension watches and alerts unified dashboard (e.g., "Export done—share to client via WhatsApp?").[35] [36] [37]

Photoshop: UXP/CEP + Event Listeners for document save/export (`action.addNotificationListener` on `saveDupeEvent`, `exportEvent`). Detect layer edits, PSD exports, errors.[38] [39]

VS Code: Build/Events

Via Extension (TS):

- `onDidChangeActiveTextEditor`, `workspace.onDidSaveTextDocument`.
- Tasks: `tasks.onDidStartTask`, `tasks.onDidEndTask` for builds (success/error).
- Terminal: Monitor output for errors.
- Payload: `{event: "build_success", task: "npm run", time: "2s"}`.

Forwards to super app for context-aware handling (e.g., suppress notifs during debug).[33]

Feasibility & MVP Demo

High for basics (8/10):

- Premiere/Photoshop CEP: Copy Adobe samples, add polling/WebSocket (2-3hrs each).
- VS Code: `yo code` generator (1hr).
- Errors/Exports: Reliable via callbacks/polling; demo with manual triggers.

Demo Flow: Install exts → Trigger export/build → Super app gets real-time notif → Auto-action (e.g., "Upload Premiere export to drive + Teams post"). Mock complex errors with buttons if needed.[37] [35]

Implementation Tips

- **Comm Protocol**: All exts use same JSON over WebSocket (ws://localhost:3000).
- **Super App**: Electron window listens, applies context ML.
- **Photoshop Specific**: UXP events for `openEvent`, `closeEvent`, exports.
- **Edge Cases**: Offline-first (local queue), permissions via user prompts.

This scales your super app to creative/dev roles seamlessly.[34] [38]

⁂

so this super app will be an website or web extension or an desktop application?

also can we send export data or other data required for this PS from premier pro/ photoshop to our system..
can we get coding metrics from the plugin extension if we create one for vs code?? and how can we send that data to our system//

Your super app should be a **desktop application** (built with Electron or Tauri) for seamless integration with offline tools like Premiere Pro, Photoshop, and VS Code—web extensions alone can't handle native app data reliably.

Super App Form

- **Desktop App (Recommended)**: Runs as tray/minimized app with dashboard window; hosts local server for extensions to connect. Offline-capable, native notifications, cross-OS. Web extension optional for browser tools.[44] [45]
- **Not Pure Web**: Limited to browser tabs; can't access native app internals.
- **Not Just Extension**: Too narrow; desktop app orchestrates everything.

Sending Data from Apps

Yes, extensions can extract and send rich data (exports, metrics) as JSON payloads over HTTP/WebSocket to super app's localhost endpoint. Permissions via user consent; secure with tokens.

Premiere Pro/Photoshop:

- **Export Data**: CEP/UXP captures export path, duration, format, thumbnail URL (via scripting); e.g., `{export: {file: "video.mp4", status: "done", size: "500MB"}}`.
- **Other Data**: Project/sequence metadata (clips, timeline length), layer info (Photoshop: opacity, visibility via `app.activeDocument.layers`). Write JSON temp file or direct POST; avoid full pixels (huge).[46] [47] [48]
- **Example**: Post-export, extension auto-sends to super app for unified alert/auto-upload.

VS Code:

- **Coding Metrics**: Yes, extensions track lines written, keystrokes, functions size, edit sessions (e.g., like code-metrics or ks-coding-stats). Use `TextDocument.onDidChangeContent` for deltas, `workspace.textDocuments` for totals.
- **Data**: `{metrics: {keystrokes: 1500, lines_added: 45, errors: 2, session_time: "2h"}}`.
- Existing inspo: GitHub repos compute real-time stats; forward via `fetch` or telemetry lib.[49] [50]

Data Flow Example

1. **Event Triggers**: Export complete (Premiere), save/build (VS Code/Photoshop).
2. **Extension Extracts**: JSON via app DOM/API (ExtendScript for Premiere, VS Code API).
3. **Send Securely**:

```
// In extension
fetch('http://localhost:3000/data', {
  method: 'POST',
  headers: {'Authorization': 'user-token'},
  body: JSON.stringify(data)
});
```

4. **Super App Receives**: Processes context, stores in local DB (SQLite), triggers actions (e.g., "Metrics show high productivity—delay notifs").

Privacy: Opt-in, local-only by default; anonymize metrics.[51]

MVP Feasibility

High: Extensions send data in <100 lines; Electron boilerplate quick. Demo: Trigger events → Live metrics/export data in dashboard.[47] [49]

⁂

now the solutin taht we have finally arrived at... give it as a architecutre flow.. the features, how it should be implemented, the feasibilty,

GIVE the SYSTEM FLOW how the centralise super app sytem communicates with everyone!! let it be power bi, let it be figma, premier pro, vs code ...

The finalized solution is a **Context-Aware Super App Layer**—a desktop Electron app acting as unified orchestrator for notifications and actions across web, cloud, and native apps, solving fragmented attention issues.

Core Features

- **Smart Notifications**: Context ML decides deliver/delay/suppress based on active app, task, behavior.
- **Unified Dashboard**: Single view of all feeds/metrics/actions.
- **Cross-App Automation**: Triggers chains (e.g., VS Code build → Premiere import → Figma update).
- **Data/Metrics Sync**: Pulls events, exports, coding stats for insights.
- **Role Profiles**: Data analyst (Power BI/Teams), Video editor (Premiere/Figma), Dev (VS Code).
- **Voice/Gamification**: Natural commands, focus scores.

High-Level Architecture

```
┌──────────────────┐    WebSocket/HTTP/      ┌──────────────────┐
│   Super App      │◄──────────────────────►│  Extensions      │
│ (Electron)       │    Localhost:3000       │ • Premiere CEP   │
│                  │                         │ • Photoshop UXP  │
├──────────────────┤                         │ • VS Code Ext    │
│ Dashboard        │    Firebase (Cloud)     │ • Chrome Ext     │
│ Context ML       │◄──────────────────────►│ • Figma (OAuth)  │
│ Local Server     │                         └──────────────────┘
│ SQLite DB        │
└──────────────────┘
        │
        ▼ (APIs/Webhooks)
┌──────────────────┐
│ Cloud Services   │
│ • Power BI Embed│
│ • WhatsApp API   │
│ • Teams Bot      │
│ • Figma API      │
└──────────────────┘
```

Desktop-first for native access; hybrid mobile via React Native companion.[54]

System Flow

1. **Onboard & Connect**:
   - User installs Super App + extensions (e.g., VSIX for VS Code, CEP ZIP for Premiere).
   - Extensions register via POST `/register` with app ID, capabilities.
   - Web/cloud: OAuth (Power BI token, Figma API key, WhatsApp webhook URL).
2. **Monitor Events** (All Apps):
   - **Native (Premiere/VS Code/Photoshop)**: Ext hooks API events (export, save, keystroke) → JSON payload → WebSocket to localhost:3000.
   - **Web/Cloud (Power BI/Figma/Teams/WhatsApp)**: Webhooks (Teams/Figma), polling (Power BI), Chrome ext content scripts.
   - Example Payload: `{source: "premiere", event: "export_complete", data: {file: "vid.mp4", metrics: {duration: 120s}}}`.
3. **Central Processing**:
   - Super App local server receives → Stores in SQLite.
   - **Context Engine** (TensorFlow.js): Analyzes (active window via OS API, keystrokes, time) → Score focus/task match.
   - Decide: Deliver (native notif + dashboard), Delay (queue till context fits), Suppress.
4. **Unified Actions**:
   - Dashboard shows aggregated feed: "Premiere export done [action: share to Figma/Teams]".

- Automation: Rules engine (e.g., VS Code metrics > threshold → "Notify team via WhatsApp").
- Cross-Send: Super app pushes back (e.g., Figma comment → VS Code terminal).

5. **Feedback Loop**:
   - Voice: "Handle export" → Routes to action.
   - Gamify: +Points for focus sessions → Dashboard charts.

Visual Flow for Data Analyst/Video Editor/Dev:

```
Event (Power BI alert) ⟶ Context Check ⟶ Delay (VS Code active) ⟶ Deliver Later ⟶ Aut
Event (Premiere export) ⟶ Metrics Sync ⟶ Action (Teams post) ⟶ Gamify Streak
```

Implementation Guide

Component	Tech	Steps
Super App	Electron + React + Socket.io + TensorFlow.js	1. electron-forge boilerplate. 2. Express server. 3. Dashboard (tabs per app). 4. ML model for context (train simple on keystrokes).
Native Exts	CEP (Premiere/Photoshop JS), VS Code (TS yo code)	1. Adobe/VS samples. 2. Event listeners. 3. POST/WebSocket data.
Web/Cloud	Chrome Ext + OAuth SDKs	1. Manifest V3. 2. Power BI JS embed. 3. Figma REST API.
Backend Sync	Firebase Functions (opt)	Webhooks → Realtime DB.
Deploy	Electron Builder (EXE/DMG)	Sign for hackathon demo.

Code Snippet (Ext to Super):

```
// Premiere CEP example
socket = new WebSocket('ws://localhost:3000');
app.project.addEventListener('exportComplete', () => {
  socket.send(JSON.stringify({app: 'premiere', event: 'export', data: {...}}));
});
```

Feasibility (24hr Hackathon)

9/10: Modular—build core Electron + 2 exts (VS Code + Chrome) first (10hrs), add Premiere/Figma mocks (4hrs), polish dashboard/ML (6hrs), demo scripts (2hrs). Free tools, live triggers wow judges. Scale post-hack with more exts.[55] [56] [57]

⁂

Extension Significance & Automation

Each extension/plugin bridges the super app to app-specific events/data, enabling context-aware notifications and automations that reduce context-switching for users.

Premiere Pro CEP Extension

Significance: Hooks into video editing workflows (exports, timeline events, renders) to capture status, metadata (duration, file path).
Automation Help: Auto-notify "Export complete—upload to Figma/Teams?" or "Error: Retry render?" Chains: Premiere export → auto-import assets to Figma or share metrics to dashboard. Saves editors 5-10min per export cycle.
Feasibility (Demo/Local): 8/10. Use Adobe CEP samples + ExtendScript polling (2-3hrs). Local: Copy to `~/Library/Application Support/Adobe/CEP/extensions/` (macOS) or equiv; load via debug mode—no upload/store needed.[58] [59]

Photoshop UXP Plugin

Significance: Monitors layer edits, saves, exports; pulls document data (layers, sizes).
Automation Help: "Layer export done—send to Premiere sequence?" or suppress notifs during batch edits. Chains: Photoshop PSD update → refresh Figma prototype or VS Code asset refs. Boosts iterative design workflows.
Feasibility (Demo/Local): 9/10. UXP Developer Tool creates starter in 5min; add events (1-2hrs). Local: UDT loads instantly in Photoshop—no signing/upload.[60] [61]

VS Code Extension

Significance: Tracks coding metrics (keystrokes, lines, builds), file events, errors.
Automation Help: "Build success—deploy preview to Figma?" or "High keystrokes—delay meetings." Chains: Code metrics → Power BI dashboard update or Premiere script generation. Quantifies dev productivity.
Feasibility (Demo/Local): 10/10. `yo code` generator + API listeners (1hr). Local: F5 debug/run in VS Code; share .vsix for team—no marketplace publish.[62] [63]

Chrome Extension

Significance: Captures browser tabs, research (Power BI embeds, Figma tabs), web notifs.
Automation Help: "Power BI refresh needed during VS Code focus? Delay." Chains: Browser research → auto-save snippets to Photoshop notes or Teams. Unifies web tools.
Feasibility (Demo/Local): 10/10. Manifest V3 boilerplate (30min). Local: Load unpacked in chrome://extensions/—instant demo.[64] [65]

Figma (OAuth Integration)

Significance: Not a traditional ext—OAuth app pulls file changes, comments, prototypes (REST API).
Automation Help: "Figma comment—notify Photoshop editor?" Chains: Figma update → import SVGs to Premiere or log metrics to VS Code. Enables design-dev handoffs.

Feasibility (Demo/Local): 9/10. Register OAuth app + fetch (1hr). Local: Personal token or test OAuth flow; no ext install, just super app handles.[66] [67]

Overall Demo Tips

Prioritize VS Code + Chrome (quick wins); total 6-8hrs for all. Each runs locally—demo multi-app chain (e.g., VS Code build → Figma refresh via super app). High wow-factor for hackathon.[58] [62]

⁂

so on all these extensions mentioned can we get real time user context—such as

active tasks, behavior, and interaction patterns… in our electon super app? will we be allowed to get the same.. like to see how much time he has spent on youtube, video editing.. if he's busy in a video editing project then at that time we should not display less priority notifications like "hii, hello or from promotional things" and should show priority notification if from manager.. schedule change etcc!!
can we pull it of as MVP in 20 hrs

Yes, all listed extensions can capture real-time user context (active tasks, behavior like keystrokes/time spent, interaction patterns) and feed it to the Electron super app—permissions are user-granted via installs, making it fully allowed and privacy-compliant.

Context Capture Capabilities

Per Extension:

- **Premiere CEP**: Tracks timeline focus, export time, edit sessions (polling `app.project.activeSequence`). E.g., "Busy editing 45min → suppress promo notifs."
- **Photoshop UXP**: Layer/task activity, brush strokes via events; session timers.
- **VS Code Ext**: Precise coding time, keystrokes (`onDidChangeTextDocument`), idle detection (like WakaTime)—e.g., "Active coding → prioritize manager alerts only."[68] [69]
- **Chrome Ext**: Tab time (YouTube 20min?), page interactions (Power BI views)—smart active tab tracking.[70] [71]
- **Figma OAuth**: File edits, comment rates via API polling/webhooks.

Global Aggregation: Electron super app uses OS APIs (`robotjs` Win, `node-mac-permissions` macOS) for active window (e.g., "Premiere front → high focus"), plus ext data for patterns. Classify: "Video editing busy" vs "YouTube low-priority."[72] [73]

Priority Logic Example:

```
Context Score = (app_category: editing=high, time_spent>30min) + behavior (keystrokes>1
If score>threshold & sender=promo: Suppress/Delay
```

```
If manager/schedule: Deliver always + badge
```

MVP Feasibility in 20 Hours

Yes, 9/10—Pull-off a compelling demo easily:

- **Core (8hrs):** Electron + context ML (TensorFlow.js simple classifier on ext payloads/OS window).
- **Exts (6hrs):** VS Code/Chrome (1hr each, templates), Premiere/Photoshop mocks or basics (1hr), Figma API (1hr).
- **Logic/Demo (4hrs):** Rules engine, scripted triggers (e.g., timer sim "YouTube 10min → promo suppressed; Teams manager → instant").
- **Polish (2hrs):** Dashboard charts, voice.

Proof: Extensions like WakaTime/YouTube trackers exist; aggregate in Electron via localhost. Hackathon demo: Live switches (VS Code → Premiere), show suppressed vs priority notifs. Free tools, no approvals needed for local runs.[73] [68] [70]

This nails the PS: Real-time context optimizes attention across apps.[74]

⁂
